<p>The <b>order</b> of a differential equation (DE) is the order of the highest derivative which occurs in the equation.</p>	<p>© 2017 Jason Underdown</p> <p>This work is licensed under a Creative Commons Attribution 4.0 International License</p> <p></p> <p><a href="https://creativecommons.org/licenses/by/4.0/">https://creativecommons.org/licenses/by/4.0/</a></p>
<p>The DE, <math>y' = F(x, y)</math>, is <b>directly integrable</b> if</p> $F(x, y) = f(x).$ <p>Such an equation may be solved by computing:</p> $y(x) = \int f(x) dx.$	<p>An <b>ODE</b> (ordinary differential equation) is a DE that only contains total derivatives.</p> <p>A <b>PDE</b> (partial differential equation) is a DE which contains at least one partial derivative.</p>
<p>An <b>initial value problem</b> or <b>IVP</b> is a differential equation coupled with at least one initial condition, for example,</p> $y' = F(x, y) \quad y(0) = y_0.$ <p>A second order IVP will require two initial conditions, <math>y(0) = y_0</math> and <math>y'(0) = v_0</math>. In general, an <math>n</math>th order IVP will require <math>n</math> initial conditions.</p>	<p>A <b>general solution</b> to a DE is any continuous function which satisfies the DE and contains at least one constant of integration.</p> <p>A general solution is actually a collection or <i>family</i> of functions parametrized by the integration constant(s).</p>
<p>Given a first-order DE, <math>y' = F(x, y)</math>, one can graphically approximate solutions to the DE by generating a <b>slope field plot</b>:</p> <ol style="list-style-type: none"> <li>1. Divide a region of the <math>xy</math>-plane into a grid.</li> <li>2. For each cell in the grid compute <math>m = F(\bar{x}, \bar{y})</math>, where <math>(\bar{x}, \bar{y})</math> is the midpoint of the cell, and plot a small bar with slope <math>m</math> centered on the point <math>(\bar{x}, \bar{y})</math>.</li> </ol>	<p>A <b>particular solution</b> is a solution to an IVP. In other words it is a single function which satisfies both the DE and any initial condition(s).</p>
$y' = F(x, y) \quad y(a) = b \quad (1)$ <p><b>If</b> <math>F(x, y)</math> and <math>F_y(x, y)</math> are both continuous on some rectangle <math>R</math> containing the point <math>(a, b)</math> in its interior, <b>then</b> there exists an open interval <math>I</math> which contains <math>a</math> such that (1) has a <i>unique</i> solution on <math>I</math>. Note that the width of <math>I</math> may be shorter than the width of <math>R</math>.</p>	$y' = F(x, y) \quad y(a) = b \quad (1)$ <p><b>If</b> <math>F(x, y)</math> is continuous on some rectangle <math>R</math> containing the point <math>(a, b)</math> in its interior, <b>then</b> there exists an open interval <math>I</math> which contains <math>a</math> such that (1) has a solution on <math>I</math>. Note that the width of <math>I</math> may be shorter than the width of <math>R</math>.</p>

<p>DEFINITION</p> <p><i>autonomous</i></p> <p>ODEs AND LINEAR ALGEBRA</p>	

<p>The <b>population model</b> describes exponential growth and decay. It is an IVP:</p> $P' = kP \quad P(0) = P_0.$ <p>This model has particular solution:</p> $P(t) = P_0 e^{kt}.$ <p>Using the particular solution to extrapolate values may not be reasonable because exponential growth is often unphysical (impossible) over a long time scale.</p>	<p>The DE <math>y' = F(x, y)</math> is called <b>separable</b> if the right hand side function can be expressed as a product of two single variable functions, for example,</p> $F(x, y) = f(x)g(y).$ <p>Such equations may be solved by “separating the variables”, that is, computing:</p> $\int \frac{1}{g(y)} dy = \int f(x) dx.$
<p>An ODE is <b>linear</b> if it can be written in the form:</p> $a_n(x)y^{(n)} + a_{n-1}(x)y^{(n-1)} + \cdots + a_1(x)y' + a_0(x)y = f(x).$ <p>Example of first and second order, <i>linear</i> ODEs:</p> $a_1(x)y' + a_0(x)y = f(x)$ $a_2(x)y'' + a_1(x)y' + a_0(x)y = f(x)$	<p>The <b>diffusion model</b> describes how something diffuses or spreads into its <i>ambient</i> environment.</p> $y' = k(A - y) \quad y(0) = y_0$ <p>This model has solution,</p> $y(t) = A - Ce^{-kt} \quad C = A - y_0.$ <p>Do not try to memorize the solution! Solve the model via separation of variables.</p>
<ol style="list-style-type: none"> <li>Put in standard form: <math>y' + p(x)y = q(x)</math>.</li> <li>Multiply both sides by <math>I(x) = e^{\int p(x)dx}</math>, and integrate: <math display="block">yI(x) = \int q(x)I(x) dx</math> </li> <li><math>y = e^{-\int p(x)dx} \left[ \int \left( q(x)e^{\int p(x)dx} \right) dx \right]</math> Don't forget the <math>+C</math> when integrating!</li> </ol>	<p>Given a linear, first order ODE:</p> $a_1(x)y' + a_0(x)y = f(x),$ <p>first divide by <math>a_1(x)</math> to yield:</p> $y' + p(x)y = q(x).$ <p>The <b>integrating factor</b> is: <math>I(x) = e^{\int p(x)dx}</math>.</p>
	<p>The DE <math>y' = F(x, y)</math> is called <b>autonomous</b> if <math>F(x, y)</math> is just a function of the dependent variable <math>y</math>, that is if:</p> $F(x, y) = g(y).$ <p>Such equations can be analyzed by finding the roots of the equation <math>g(y) = 0</math> and then creating a phase diagram.</p>
